## INTRODUCTION

The COVID-19 dataset (Table 1) was selected because it had a type of information the author had never analyzed before: epidemiological data. The dataset contains information of population, COVID-19 cases/deaths/tests and variable rates for 230 regions, either countries, overseas regions and others. The “World” row was eliminated and a new column “Case Fatality Rate” (deaths/cases\*100) was introduced. This dataset aims to be a census, not a sample. However, since 2024 it stopped updating data, so the analysis is performed with the April 13th 2024 situation and some fields for certain countries are missing (NA values). Results are presented in this poster-like format because of its originality and fancy design for the reader.

**Table 1:** 10 first entries of the used COVID-19 dataset.

order	Country_Other	Total_Cases	Total_Deaths	Total_Recovered	Active_Cases	Tot_Cases.1M_pop	Deaths.1M_pop	Total_Tests	Tests.1M_pop	Population
1	USA	98572011	1087976	95773910	1710125	294139	3247	1122147003	3348488	335120523

## USE OF AI DECLARATION

I'm completing an assignment for my subject Core Bioinformatics (Statistics Module). I want you to act as a bioinformatics / biostatistics / epidemiology / R programmer expert to help me solving this exercise. I don't want you to provide me direct answers, but tips, suggestions, key changes... that help me understand the analysed data and provide an excellent analysis.

DeepThink Search

About the previous code, I want you to provide me improvements for what I have already done, search errors and explain them to me, explain the second's line syntax (I obtained it from Stack Overflow and I do not completely understand it) and purpose other steps to continue with the analysis.

DeepThink Search

The author declares that he used generative-AI resource DeepSeek to assist him during the data analysis. Two clear examples of its usage are provided in Fig. 1. Using this tool allowed a faster and further analysis while learning new insights in R syntax, packages and general options.

**Fig. 1:** Examples of prompts sent to DeepSeek.

## HYPOTHESIS & QUESTIONS

With the analysis of this data it is aimed to answer to these questions:

- Do any of the rates (Cases/M, Deaths/M, Tests/M or Death rate) follow a normal distribution?
- Which countries or zones had higher rates for testing, cases and deaths?

And test these hypotheses:

- There is a correlation between Cases/M and Deaths/M.
- There is a correlation between Cases/M and Tests/M.
- There is a correlation between Population size and Tests/M.
- There is a correlation between Tests/M and Deaths/M.

## DESCRIPTIVE STATISTICS

Initial descriptive analysis (Fig. 2) show an extreme disparity among countries, with high differences between medians and means and extremely large minmax ranges.

Tot_Cases.1M_pop	Deaths.1M_pop	Tests.1M_pop	Death_Rate
Min. : 16	Min. : 2.0	Min. : 2499	Min. : 0.00155
1st Qu.: 10898	1st Qu.: 133.5	1st Qu.: 142138	1st Qu.: 0.35091
Median : 92506	Median : 615.0	Median : 850715	Median : 0.87055
Mean :162096	Mean :1108.5	Mean : 2034940	Mean : 2.09527
3rd Qu.:269809	3rd Qu.:1763.5	3rd Qu.: 2331568	3rd Qu.: 2.05695
Max. :617517	Max. :6373.0	Max. :22006216	Max. :25.42819
NA's :2	NA's :7	NA's :16	NA's :5

**Fig. 2:** Trimmed screenshot of R's output for summary(dataset).

# DISTRIBUTIONS

The distributions of Cases, Tests and Deaths per 1 Million population, as well as of Case Fatality Rate (CFR), were plotted (Fig. 3-6) to visually inspect them. The top 10 countries' values for each variable were also plotted (Fig. 3-6) to visually inspect differences or tendencies. To extract meaningful conclusions of these type of analysis, they should include other socioeconomic and geographical data. For these reason, the comments on this part are merely descriptive, with no epidemiological conclusions.

Fig. 3: Cases/M distribution and top 10 countries.

Not normally distributed, with low values being the more frequent.

Top 10 regions are mainly European countries and there is a high diversity of population size.

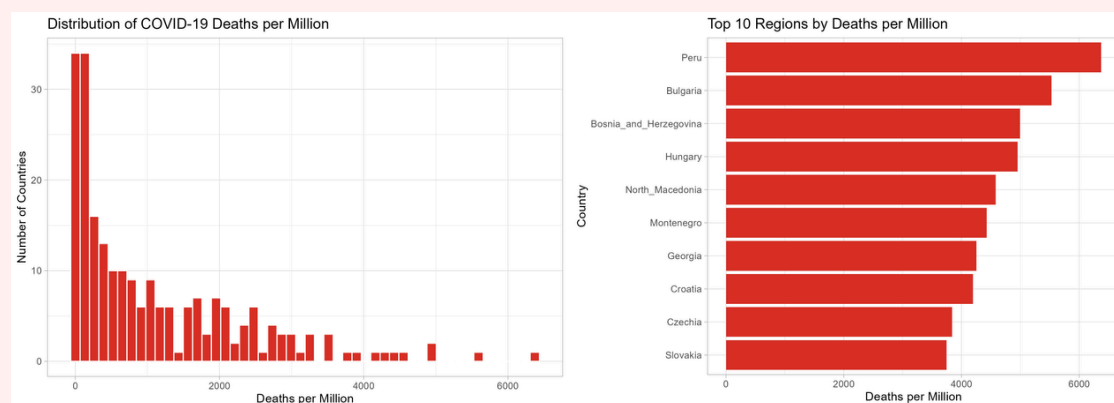

Fig. 4: Deaths/M distribution and top 10 countries.

Not normally distributed, with low values being the more frequent.

Top 10 regions are all east-European countries, despite Peru. All of them are mid-sized countries.

Fig. 5: Tests/M distribution and top 10 countries.

Not normally distributed, with low values being the more frequent.

Top 10 regions are all European countries or overseas territories. and there is a high diversity of population size.

Fig. 6: CFR distribution and top 10 countries.

Not normally distributed, with low values being the more frequent.

Top 10 regions are African and Asian countries + the famous case of the Zaandam cruise ship.

# CORRELATIONS

The rate variables were tested with each other to search for interesting correlations using Spearman Correlation Test. NA values were discarded. The hypotheses set was:

- $H_0: \rho = 0 \rightarrow$  No correlation between variables.
- $H_1: \rho \neq 0 \rightarrow$  Correlation between variables (considering a two-sided test, as we are interested in both positive and negative correlations).

## Cases/M VS Deaths/M (Fig. 7)

Significant moderate positive correlation.

- **p:** 0.6493
- **p-value:**  $4.3973 \times 10^{-28}$

This was the expected trend, as more cases rate in a country is expected to generate a higher Deaths/M. This relation could fluctuate due to many factors, such as public healthcare, which makes the correlation be lower than if every country was equal.

**Fig. 7:** Relation between Cases/M and Deaths/M.

## Tests/M VS Cases/M (Fig. 8)

Significant high positive correlation.

- **p:** 0.8139
- **p-value:**  $\sim 0$

More testing implies detecting more cases and, in turn, countries with more cases tend to adopt testing politics to avoid further propagation of the virus. The association is consistent with this possible explanation.

**Fig. 8:** Relation between Tests/M and Cases/M.

## Population VS Cases/M (Fig. 9)

Significant moderate negative correlation.

- **p:** -0.3909
- **p-value:**  $1.3227 \times 10^{-9}$ .

The correlation is barely moderate because it is extremely multifactorial and there are contradictory arguments. For example, larger populations could be related to advanced society and better hygiene but also more interconnected mass groups.

**Fig. 9:** Relation between Population size and Cases/M.

## Did COVID-19 testing cause an increase of the deaths? Tests/M vs Deaths/M (Fig. 10)

Significant moderate positive correlation.

- **p:** 0.5942
- **p-value:**  $1.0226 \times 10^{-21}$

**Fig. 10:** Relation between Tests/M and Deaths/M.

However, this is a clear example that correlation does not imply causation. In these cases, there often is a hidden variable that explains this weird correlation. It is clear that the COVID-19 testing is not an invasive intervention that caused thousands of deaths, but an easy way to track the pandemic development and help improving population's security. Thanks to the previous correlations calculations, we can see that there are positive correlations between Tests/M and Cases/M, and Cases/M and Deaths/M. Then, we could have found the hidden third variable: Cases/M. More testing is correlated with more COVID-19 cases rate, which is correlated with a higher Deaths/M.

To sum up, although testing rate is positively correlated with Deaths/M, it is not a causal factor of it.

## SUMMARY OF CONCLUSIONS

- The analysed variables of the dataset show irregular distributions with shallow trends.
- Top 10 Cases/M and Tests/M is mainly European, Deaths/M east-European and CFR African/Asian.
- Cases/M was found to be correlated with Deaths/M and Tests/M. This is used as a hypotheses to explain the found correlation between Tests/M and Deaths/M.
- A shallow negative correlation was found between population size and Cases/M.
